

PATENT CLAIMS

1. A method for transmitting binary data at a rate of R bits per second via a dispersive optical conductor (3) of length d between a transmitter (1) and a receiver (2), where
- a) the transmitter (1) comprises a light source (11) which produces optical pulses with a transmission pulse width τ ,
- b) the pulses are passed through the optical conductor (3) to the receiver (2) and in the process are broadened by a value $\Delta\tau$ as a consequence of the optical conductor (3) having a dispersive characteristic,
- c) the receiver comprises a light detector, in which the optical pulses arrive with a reception pulse width $\tau + \Delta\tau$, characterized in that
- d) the transmission pulse width τ is less than one bit period $1/R$, and the reception pulse width $\tau + \Delta\tau$ is approximately equal to one bit period $1/R$.
2. The method as claimed in claim 1, characterized in that the transmission pulse width τ is selected as a function of the transmission distance d.
3. The method as claimed in claim 1, characterized in that a sequence of pulses at the receiver (2) at least approximately represents an NRZ signal.
4. The method as claimed in claim 1, characterized in that the distance d is more than 500 km.
5. The method as claimed in claim 1, characterized in that said method is used for synchronous data transmission.
